

3.2: Quadratic functions

Definition.

A quadratic is a function of degree two. The **general form of a quadratic function** is

$$f(x) = ax^2 + bx + c \quad (a \neq 0)$$

where a , b , and c represent constants. The **standard form of a quadratic** is

$$f(x) = a(x - h)^2 + k.$$

A **parabola** is the shape of the graph of a quadratic function, with a vertex at (h, k) :

$$h = -\frac{b}{2a}, \quad \text{and} \quad k = f(h) = c - \frac{b^2}{4a}$$

The optimal value occurs at the vertex of a parabola:

- A maximum if $a < 0$ 
- A minimum if $a > 0$ 

Example. Find the vertex of the following quadratic functions by

- computing h and k , and
- rewriting the quadratic in standard form by completing the square.

Identify if the vertex is the maximum or minimum value.

$$f(x) = 2x^2 - 6x + 7$$

$$g(x) = 13 - 3x^2 + 4x$$

Example. For the following quadratic functions, find

- the x and y -intercepts,
- the vertex, and
- the domain and range.

$$f(x) = 3x^2 + 2x - 4$$

$$g(x) = -(x + 2)^2 - 1$$

Example. A backyard farmer wants to enclose a rectangular space for a new garden within her fenced backyard. She has purchased 80 feet of wire fencing to enclose three sides, and she will use a section of the backyard fence as the fourth side (see below). What dimensions should she use to maximize the enclosed area?
